Abstract

A total of 108 single nucleotide polymorphism (SNP) markers from the Iwagaki oyster, *Crassostrea nipponica* were isolated and characterized based on high-throughput sequencing in this study. The minor allele frequency per locus ranged from 0.0167 to 0.4844. The observed heterozygosity and expected heterozygosity varied from 0 to 0.9688 and 0.0333 to 0.5079, respectively. Eighteen loci showed significant deviation from Hardy–Weinberg equilibrium. These SNP markers described in this study will provide a valuable tool for population genetic analysis and natural resource conservation of *C. nipponica*.

Keywords *Crassostrea nipponica* · SNP · High-throughput sequencing · High resolution melting

The Iwagaki oyster *Crassostrea nipponica* is a commercially important bivalve, which is distributed along the coasts of Japan, Korea and China (Boudry et al. 2003; Itoh et al. 2004; Yoon et al. 2008). The commercial price of *C. nipponica* is nearly five times as high as that of the Pacific oyster *C. gigas* in Japan, as it is edible during the summer when the other oyster species are unavailable (Itoh et al. 2004). Since the production of *C. nipponica* is based almost exclusively on natural stocks, over-exploitation has led to continuing decline of the natural populations over the decades (Fujiwara 1995; Li 2007). Therefore, it is urgent to perform population genetic investigation on *C. nipponica* to conserve the wild resources. Single nucleotide polymorphisms (SNPs) are now the most popular DNA markers in genetic studies because of their high level of polymorphism, favorable reproducibility and wide genomic distribution (Vignal et al. 2002). With the rapid development on next generation sequencing technologies, discovery of large numbers of SNPs in any non-model organisms of interest is becoming easier and faster. In this study, we developed and characterized SNP markers in *C. nipponica* for the first time based on the restriction-site

associated DNA (RAD) sequencing. These markers will facilitate the researches on conservation genetics and genetic evaluation in *C. nipponica*.

To obtain SNP marker resources, the RAD libraries were constructed and sequenced on the Illumina HiSeq 2500 platform using 150-bp paired-end reads. A total of 538,594 putative SNPs in *C. nipponica* was identified, of which C/T and G/A were the most common substitution and the ratio of transition to transversion was 1.22. Four hundred and twenty putative SNPs were randomly chosen for primer design using Primer Premier 5.0 and evaluated for polymorphism by high resolution melting (HRM) analysis in a cultured population of *C. nipponica* from Yantai, China ($n=32$). Genomic DNA was extracted from adductor muscle by standard proteinase K digestion and phenol–chloroform extraction. PCR was performed in a total volume of 10 μ L on a Light Cycler® 480 real-time PCR instrument (Roche Diagnostics Burgess Hill, UK). The reaction mixture contained 0.25 U Taq DNA polymerase (Takara, Dalian, China), 10 \times PCR buffer, 0.2 mM dNTP mix, 0.4 μ M of each primer set, 1.5 mM MgCl₂, 5 μ M SYTO9 (Invitrogen Foster City, CA, USA), and about 10 ng template DNA. The PCR amplification procedure was as follows: first denaturation at 95 °C for 5 min, then 45–55 cycles of denaturation at 95 °C for 40 s, annealing and extension for 40 s at 62 °C for the first cycle and thereafter at 0.5 °C decrease each for 10 cycles, and a final extension at 72 °C for 40 s. Following amplification, the products were denatured at 95 °C for 1 min, and then annealed at 40 °C for 1 min to randomly form DNA duplexes. Melting curves were

Ho observed heterozygosity, *He* expected heterozygosity, MAF minor allele frequency, *F_{IS}* inbreeding coefficient, *P_{HWE}*, the *P* values for Hardy–Weinberg equilibrium test (**P*<0.05/108=0.0005)

generated by heating samples from 60 to 90 °C with 25 data acquisitions per degree. At the end of each PCR reaction, the Light Cycler® 480 Gene Scanning Software was used to determine genotypes by analyzing the peaks in the melting curve. The minor allele frequency (MAF), expected heterozygosity (H_e), observed heterozygosity (H_o), inbreeding coefficient (F_{IS} ; Weir and Cockerham 1984) and χ^2 tests of deviations from Hardy–Weinberg equilibrium (HWE) were calculated using Popgene 1.32 (Yeh et al. 2000).

Of the 420 primer pairs, 108 SNP loci (25%) were polymorphic and produced distinct melting curves that can be genotyped by HRM (Table 1). The minor allele frequency was detected to be from 0.0167 to 0.4844. The observed heterozygosity (H_o) and expected heterozygosity (H_e) varied from 0 to 0.9688 and 0.0333 to 0.5079, respectively. The values of F_{IS} were estimated from –0.9394 to 1.0000. Eighteen SNPs showed significant deviation from HWE after the Bonferroni correction ($P < 0.0005$). These polymorphic SNP markers will be useful for further population genetic analysis, natural resource conservation and selective breeding of *C. nippona*.
